Dear Editor,

Palmoplantar pustulosis (PPP) is a refractory inflammatory disease characterized by pustular eruptions on the palms and soles.¹⁻³ The etiology of PPP is unknown, but it may be caused by metal allergy, tonsilitis, and smoking.¹⁻⁴ The mechanism by which metal allergy causes PPP has not been elucidated yet. A systematic review of 519 patients with PPP revealed that metal allergens triggered PPP.³ Conversely, another retrospective analysis suggested that dental metal removal did not improve PPP symptoms.¹ Herein, we report a case with PPP presenting with recurrence of non-bacterial pustular eruptions only at the site of insertion of therapeutic titanium for bone fracture healing.

A 62-year-old man had PPP on the palms and soles for 15 years and had been in remission at the time of the present case report. The patient had a bone fracture in his left lower leg, which was treated with a therapeutic titanium implant. After 5 months, he presented with non-bacterial pustular eruptions with erythematous scaling only at the site of insertion of therapeutic titanium (Figure 1a–e). The skin biopsy from the pustule on the left lower leg showed PPP manifestations (Figure 1f). First, we hypothesized that the operation led to an eccrine sweat glands disorder resulting in sweat leakage in the dermis of the affected area. However, a thermoregulatory sweat test using the

starch-iodine method with sweating revealed neither hypohidrosis nor hyperhidrosis of the affected area (Figure 1g–h).⁵ Moreover, immunohistochemical staining for dermcidin, the major sweat antimicrobial peptide, did not show sweat leakage (Figure 1i–j).⁵ The patch test with metal allergens revealed the erythema result for titanium and iron, both of which are included in the insertion although the iron content is low (<1%) (Figure 1k). Patient's symptoms responded to the difluprednate ointment, but when the treatment was discontinued the symptoms recurred.

PPP may be caused by various factors.^{1,3,4} In the present study, we showed that the potential contribution of metal allergy to the etiology of PPP is in line with the systematic review by Brunasso et al.³ However, no similar cases have been reported and it is difficult to confirm whether a metal allergy is the main cause, because therapeutic titanium cannot be removed from the bone. Also, it is challenging to propose a mechanism explaining how it would lead to the symptoms of PPP. Although titanium allergy is rare, titanium used for orthopedic surgery for left distal radius fracture reportedly led to PPP.⁴ Murakami et al. performed the immunohistochemical staining of dermcidin as a maker for sweat secretion and revealed the contribution of the abnormal eccrine sweating to PPP.² However, the sweat secretion, as well as sweat function, were normal in this case. Further studies are needed to elucidate the mechanism through

75	which metal allergies cause PPP, and whether the Koebner phenomenon by bone
76	fracture and/or operation may induce a PPP lesion. Nevertheless, our results show the
77	potential contribution of metal allergy to PPP etiology.
