The reaction of $HAuCl_4 \cdot 4H_2O$ and *n*-$C_{12}H_{25}SH$ with 1 equiv of Et_3SiH in an organic solvent affords spherical gold nanoparticle (AuNP) with narrow dispersity.

Gold nanoparticle (AuNP) has attracted considerable attention for applications to catalysis, nonlinear optical material and biological sensing due to its characteristic magnetic, electronic and optical properties.[1] Since size of the nanoparticle gives significant effect to its properties, development of synthetic methodologies for the preparation of AuNP with narrow dispersity becomes highly important. AuNPs have been generally synthesized under biphasic conditions in a mixure of aqueous and organic solvent system with sodium borohydride as a reducing agent in the presence of quaternary ammonium salt as a phase transfer catalyst.[2] On the other hand, synthesis of AuNPs in a single-phase system has been performed with stronger hydride ions such as $LiBH_4$,[3] amine-borane complex,[4] and superhydride ($LiBHEt_3$).[5,6] These reactions are carried out under anhydrous conditions since the hydride reacts vigorously with water and protocols generally employ large excess of the reducing agent. Organosilanes react with a variety of carbon-carbon and carbon-heteroatom unsaturated bonds through the addition of hydrogen and silicon atoms, namely hydrosilylation, and have been widely utilized in organic synthesis.[7] As the silicon-hydrogen bond is less ionic and stable to water, hydrosilylation reactions have been carried out by transition metal catalysis.[8] Several other functional groups are tolerable for the reaction with silane reagents, accordingly. In addition, organosilanes are less toxic and the use of which is thereby a potentially environmentally benign process. Preparation of AuNPs with organosilanes as a reducing agent, if successful, the protocol that is performed in an organic solvent under mild conditions is intriguing. We herein describe that triethylsilane is a highly effective reducing agent for the single-phase preparation of thiol-capped AuNPs.

Synthesis of AuNP was carried out by the following procedure. A solution of $HAuCl_4 \cdot 4H_2O$ (0.1 mmol) and dodecanethiol (0.1 mmol) in 10 mL of THF was vigorously stirred for 3 h at 25 ˚C. To the resulting yellow solution triethylsilane was added dropwise at 25 ˚C to form a purple solution immediately. After stirring for 6 h at 25 ˚C, ethanol was added to the solution to precipitate AuNP, which was centrifuged to isolate the thiol-capped AuNP (**1**, 15.1 mg) as dark brown powder.

The obtained **1** was found to be dispersible to organic solvents such as THF or $CHCl_3$ suggesting that aggregation did not occur during the isolation procedure.

It should be pointed out that the preparation of AuNP performed with 1 molar amount of triethylsilane towards $HAuCl_4$ and alkanethiol represents high synthetic efficiency. The advantage would be caused by the characteristics of Et_3SiH that is unreactive towards water in $HAuCl_4$ and hydrogen chloride formed by the reduction of the gold species. Indeed, the reaction with an increased amount of Et_3SiH did not improve the yield of **1**.[9] Since synthesis of AuNPs has been generally carried out with excess amounts of reducing agent, it is remarkable that the use of 1 equivalent of Et_3SiH can undergo the formation of AuNP. Worthy of note, in addition, is the AuNP preparation in an organic solvent as a single phase medium. According to Blackmond,[10] the process to cause contamination of water by organic compounds, which may cause in the reaction with a water-organic solvent system, is *environmentally unfriendly*. Therefore, the preparation in THF with 1 equiv of less toxic Et_3SiH under mild conditions is an *environmentally benign* protocol.

$$HAuCl_4\text{-}4H_2O + HS{-}nC_{12}H_{25} \xrightarrow[THF]{Et_3SiH} \underset{\mathbf{1}}{\text{gold nanoparticle}} \quad (1)$$

Characterization of obtained AuNP **1** was carried out by measurements of TEM images, UV-vis spectra, and ^1H NMR analyses. Fig. 1 shows the TEM image of the AuNP, which is spherical and exhibits an average diameter of 8.6±0.65 nm indicating the formation of unaggregated and highly monodispersed AuNP. UV-vis spectrum of the AuNP was shown in Fig. 2. The λ_{max} value of the UV-vis spectrum was observed at 528 nm, which is attributed to characteristic plasmon resonance absorption of AuNP.[1] The ^1H NMR spectrum of AuNP as a solution of $CDCl_3$ exhibited triplet signal at δ 0.88 and broad signal at δ 1.26, respectively, which are assigned to CH_3- and CH_2- of dodecanethiol adsorped on the surface of AuNP.

Table 1 summarizes the results on the scope and limitation for the preparation of AuNP with Et_3SiH. It is highly important to stir the mixture of dodecanethiol and $HAuCl_4$ for longer than 3 h before addition of the reducing agent to prepare monodisperse AuNP. Stirring for a shorter period resulted in agglomeration of the nanoparticle, which was confirmed by TEM analyses. Although other organosilanes, diethoxy(methyl)silane and pentamethyldisiloxane were found to form purple solution immediately similar to Et_3SiH, nonspherical nanoparticles ranging in size from 6-60 nm were obtained. Treatment of tetramethyldisiloxane $(HMe_2Si)_2O$, and poly(methylhydrosiloxane) [PMHS: $(HMeSiO)_n$] were found to be ineffective to observe precipitation of insoluble flocculated product.[11] Among several solvents examined, di-*n*-butyl ether (9.3±0.91 nm), cyclopentyl methyl ether (8.8±0.58 nm), tert-butyl methyl ether (9.5±0.84 nm) were found to form monodisperse nanoparticles, while other solvents such as diethyl ether, 1,4-dioxane, 1,2-dimethoxyethane (DME) and methoxybenzene did not afford monodisperse nanoparticle. The key for the success to form monodisperse gold nanoparticle would probably due to the formation of homogeneous solution of the intermediate gold thiolate in THF di-*n*-butyl ether cyclopentyl methyl ether and *tert*-butyl methyl ether, while the use solvents such as diethyl ether, 1,4-dioxane, etc. formed precipitation in the reaction of $HAuCl_4 \cdot 4H_2O$ and dodecanethiol. Other organic solvents such as dichloromethane and toluene were found to be ineffective since $HAuCl_4$ was not dissolved at all .

Table 1 Formation of AuNP with a silane reagent.[a]

entry	silane	solvent	yield, mg	size, nm
1	Et_3SiH	THF	15.1	8.6±0.65
2	Et_3SiH[b]		15.7	8.4±0.64
3	$HSiMe(OEt)_2$	THF	8.9	-[c]
4	$HMe_2SiOSiMe_3$		18.0	-[c]
5	$(HMe_2Si)_2O$		-[d]	-
6	$(HMeSiO)_n$		-[d]	-
7	Et_3SiH	$^nBu_2O$	13.2	9.3±0.91
8		CPME[e]	14.6	8.8±0.58
9		$^tBuOCH_3$	8.9	9.5±0.84
10		Et_2O	-[f]	-
11		1,4-dioxane	-[f]	-
12		DME	-[f]	-
13		$PhOCH_3$	-[f]	-

a) Unless noted, the reaction was performed with dodecanethiol (0.1 mmol), $HAuCl_4 \cdot 4H_2O$ (0.1 mmol) and Et_3SiH (0.1 mmol) with 10 mL of the solvent at 25 ˚C. b) 10.0 mmol of Et_3SiH was employed. c) nonspherical nanoparticles ranging in size from 6-60 nm formed. d) Insoluble precipitate formed. e) Cyclopentyl methyl ether. f) Precipitation formed during the reaction of $HAuCl_4$ with thiol.

The size of AuNP was found to be dependent on the reaction temperature. The addition of triethylsilane to a THF solution of $HAuCl_4 \cdot 4H_2O$ and dodecanethiol at 0 ˚C afforded 9.3 mg of 7.5±0.57 nm nanoparticles after stirring for 24 h. On the other hand, the reaction at 50 ˚C furnished 17.3 mg of 10.0±0.90 nm nanoparticles within 3 h (Figure 3a, b). In contrast to the single-phase method using superhydride or $LiBH_4$ which was a stronger reducing agent, afforded AuNP in the range of 2-4 nm,[5] the use of triethylsilane produced AuNP of larger size, 7-10 nm. Accordingly, the size of gold nanoparticle would be dependent of the reduction rate of gold thiolate, which is rapidly reduced by a strong metal hydride to afford smaller nanoparticles or by the use of not a large excess amount of the mild reducing agent, Et_3SiH to bring about the reduction of the thiolate in a reasonable rate leading to the size of 7.5-10.0 nm.

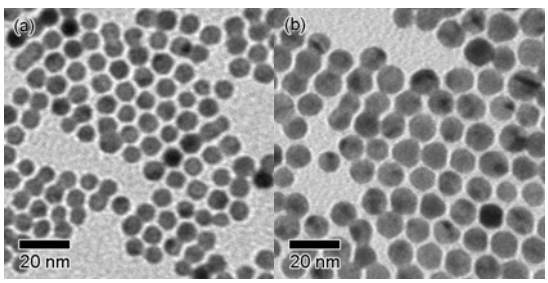

Fig. 3 (a) TEM image of AuNP synthesized at 0 ˚C (7.5±0.57 nm). (b) TEM image of AuNP synthesized at 50 ˚C (10±0.9 nm).

In summary, gold nanoparticles were found to be generated by the reaction of dodecanethiol and $HAuCl_4$ in the presence of triethylsilane as a new class of reducing agent. The formed AuNPs exhibited 7-10 nm of spherical particle with high monodispersity. Since the nanoparticle was prepared with 1 equivalent of organosilane in an organic solvent as a single phase, the protocol is highly efficient and environmentally

benign process.
