1 **Abstract**

2 **Objective:** The purpose of this study was to clarify the impact of  
3 superficial parotidectomy and postoperative radiotherapy (PORT) for the  
4 surgical treatment of early stage squamous cell carcinoma (SCC) in  
5 external auditory canal (EAC).

6 **Materials and Methods:** Thirty-seven patients with T1 (n=14) or T2 (n=19)  
7 SCC in EAC treated between 2000 and 2016 at Kobe University Hospital were  
8 enrolled in this study. Thirty-three patients were operated with sleeve  
9 resection or lateral temporal bone resection.

10 **Results:** The 5-year overall survival and disease-specific survival rates  
11 were 95% and 100%, respectively. Surgical margin was positive in 4  
12 patients, who were treated by PORT and have been alive without disease.  
13 Prophylactic superficial parotidectomy was simultaneously performed at  
14 the time of initial surgery in 15 patients, in whom no lymph node (LN)  
15 metastasis was observed. Among the other 22 patients, regional recurrence  
16 in parotid LN was observed in one patient, who was successfully salvaged  
17 by total parotidectomy. Potential parotid lymph node metastasis rates of  
18 T1 and T2 SCC in EAC was 0% (0/14) and 5%(1/19) respectively.

19 **Conclusions:** Complete resection without positive surgical margins is  
20 essential for the treatment of the patients with T1 and T2 ear cancers.  
21 Prophylactic superficial parotidectomy or neck dissection is not  
22 mandatory for T1 and T2 diseases, as long as precisely extent of disease  
23 is assessed preoperatively. PORT should be performed for the patients  
24 with positive surgical margins.

## 1 Introduction

2 Squamous cell carcinoma of the external auditory canal (EAC) is extremely  
3 rare with an annual incidence estimated at between 1 to 6 cases per  
4 million of the populations.<sup>1)</sup> For early stages T1 and T2, as defined by  
5 the modified Pittsburgh staging system <sup>2)</sup>, sleeve resection of the external  
6 canal or *en bloc* lateral temporal bone resection (LTBR), have yielded  
7 favorable oncological and functional results and are the treatment of  
8 choice at most institutions.<sup>3) 4) 5)</sup> According to the United Kingdom  
9 National Multidisciplinary Guidelines published in 2016,<sup>6)</sup> LTBR is  
10 regarded as the minimum oncologic operation for T1 and T2 lesions.  
11 Prophylactic superficial or total parotidectomy is recommended for all  
12 resections. Post-operative radiotherapy (RT) or chemoradiotherapy (CRT)  
13 is recommended for most T2-T4 disease, with the exception of T1 and  
14 selected T2 without particularly peri-neural infiltration and with clear  
15 margins. However, these guidelines were based on small number reports,  
16 and the indication of parotidectomy and postoperative radiotherapy (PORT)  
17 for T1 and T2 patients is not clearly determined at present. The purpose  
18 of this study was to clarify the impact of superficial parotidectomy and  
19 postoperative radiotherapy (PORT) for the surgical treatment of early EAC  
20 cancer.

21

## 22 Materials and Methods

23 Between 2000 and 2016, 99 consecutive patients with squamous cell  
24 carcinoma arising from external auditory canal were treated at Kobe  
25 University Hospital. Among them, 37 patients with T1 or T2 tumor were  
26 enrolled in this study. All patients were pathologically diagnosed as

1 having squamous cell carcinoma of the external auditory canal. At the  
2 initial diagnosis, extent of disease was assessed with the aid of  
3 contrast computerized tomography (CT) scan, magnetic resonance imaging  
4 (MRI), and 18-fluoro-2-deoxyglucose positron emission tomography (FDG-  
5 PET). Diseases were staged according to the most recent version of the  
6 modified Pittsburgh classification (2000)<sup>2)</sup>.

7         Thirty-three patients were surgically treated with sleeve resection  
8 or lateral temporal bone resection (LTBR). The other 4 patients were treated  
9 with radiotherapy (n=3) or proton beam therapy (n=1), due to patient's  
10 refusal or to physical condition and co-existing diseases. Postoperative  
11 RT was employed in surgically treated patients only whose surgical margin  
12 was positive. Patients with close to margin (<3mm), perineural invasion,  
13 or bone invasion were only observed carefully without PORT.

14         We describe the indication of resection for T1 EAC cancer. Only if a  
15 tumor located in a limited area of EAC and a whole tumor was observable  
16 with appropriate surgical margins, we performed sleeve resection. We  
17 performed LTBR, when the tumor didn't meet the above conditions.

18         For LTBR, the bony external auditory canal, tympanic membrane,  
19 malleus and incus were resected with extended mastoidectomy in an en bloc  
20 manner. The superficial lobe of the parotid gland was prophylactically  
21 resected in most T2 cases and the facial nerve was preserved in all cases.  
22 For T1 patients, if the tumor existed mainly in an anterior-inferior canal  
23 wall, we preferably resected a superficial lobe of parotid gland. LN  
24 metastases were not clinically observed in neck or parotid gland in any  
25 patient. Thus, no patients underwent prophylactic neck dissection.

26         Medical records were retrospectively reviewed to obtain information

1 concerning characteristics of the patients, extent of disease, surgical  
2 procedures including parotidectomy, metastasis of parotid LN, PORT, and  
3 oncological results. Kaplan-Meier plots were used to summarize time to  
4 event measured from the end of the first treatment. R software (Ver.  
5 3.0.2. 2013. The R foundation for Statistical Computing, Vienna, Austria)  
6 was used for the statistical analysis. This study was approved by Kobe  
7 University Hospital Internal Review Board.

8

## 9 Results

10 The characteristics of the patients are summarized in [Table 1](#). The age of  
11 the patients ranged from 38 to 94 years old with a median age of 68 years  
12 and the follow-up period ranged from 7 to 134 months (median: 60 months,  
13 average: 55.0 months). The primary diseases were classified as T1 in 17  
14 patients and as T2 in 20 patients. Of the patients with T1 disease, 3  
15 were treated with RT alone, 6 with sleeve resection, and 8 with LTBR.  
16 Among the patients with T2 disease, one was treated with proton beam  
17 therapy, and 19 with LTBR.

18 Details of the surgically treated 33 patients are summarized in  
19 [Table 2](#). Of the 14 surgically treated patients with T1 disease, 2  
20 patients had PORT due to positive surgical margins. Superficial  
21 parotidectomy was performed in 3 patients whose tumor located in an  
22 anterior-inferior canal wall. However, metastasis to the parotid lymph  
23 node or direct invasion to parotid gland was not observed in any patient.  
24 Among the 14 patients, one patient treated with sleeve resection with  
25 positive margin had local recurrence, but was successfully salvaged by  
26 LTBR. During the following-up period, one patient treated with RT alone

1 died of other disease, but other patients have been alive with no  
2 evidence of disease.

3         Of the 19 surgically treated patients with T2 disease, 3 patients  
4 had PORT because 2 of them had a positive surgical margin and another one  
5 was diagnosed in spindle cell variant squamous cell carcinoma without  
6 positive surgical margin. Superficial parotidectomy was performed in 12  
7 patients. No patients had the metastasis in parotid lymph node or direct  
8 invasion to the parotid gland. Local recurrence was observed in no  
9 patient. Among the 7 patients who did not have prophylactic superficial  
10 parotidectomy, regional recurrence in the parotid LN was observed in one  
11 patient, who were successfully salvaged by total parotidectomy. Primary  
12 disease involved to anterior-inferior canal wall in this patient. Thus,  
13 we recommended simultaneous superficial parotidectomy at the time of  
14 initial surgery, but she refused parotidectomy. During the following-up  
15 period, 3 patients died of other disease and other patients have been  
16 alive with no evidence of disease.

17         Patients treated by RT or proton beam therapy also have been alive  
18 without disease. The 5-year overall survival rates of the patients with  
19 T1 and T2 diseases were 94% and 95%, respectively. Disease-specific  
20 survival rates of the patients with T1 and T2 diseases were 100% and  
21 100%, respectively. Local control rates of the patients with T1 and T2  
22 diseases were 94% and 95%, respectively (Fig. 1). Facial nerve was  
23 preserved in all patients and no permanent facial paralysis was observed.

24         Peri-neural invasion was observed in 3 patients with T2, and 1  
25 patient with T1. One patient underwent PORT followed by surgical  
26 extirpation due to positive margin, but other 3 patients did not undergo

1 PORT. Bone invasion was observed in 18 patients out of 19 clinical T2  
2 patients, and in 2 patients out of 14 clinical T1 patients.

3

## 1 Discussion

2 Due to its rarity and aggressive oncological behavior, standard  
3 treatment for temporal bone cancer has not been established yet.  
4 For most reported cases, treatment consisting of surgical  
5 resection and postoperative RT has been selected.<sup>6)-10)</sup>  
6 Especially, cure rates of the early lesions (T1 and T2) treated  
7 by en-bloc resection were near to 100%.<sup>6)</sup> Relatively favorable  
8 oncological results have been reported on radiotherapy alone for  
9 T1 and T2 by Murai et al<sup>11)</sup>. They reported that local control  
10 rate of T1 and T2 patients is 70%. Although, all the patients  
11 treated by radiotherapy have been alive without disease in our  
12 series, radiotherapy alone may not be a first-line choice of  
13 treatment for T1 and T2 disease in the patients without serious  
14 co-existing disease and/or physical condition.

15 Indication of prophylactic parotidectomy and neck  
16 dissection, or PORT have not been established yet. Zhang et al<sup>12)</sup>  
17 reported that tumor had invaded the parotid gland directly 2/6  
18 in T1 patients and 5/11 in T2 patients. One patient with T2 had  
19 a metastatic lymph node in superficial parotid gland. From these  
20 results, they suggested that superficial parotidectomy was  
21 necessary for patients with an early stage cancer. In response  
22 to their remarks, Homer et al<sup>6)</sup> recommended total parotidectomy  
23 for advanced T3 or T4 tumor. They recommended also at least a  
24 superficial parotidectomy for all resection in UK official

1 guidelines. In another report by Prasad et al<sup>13)</sup>, the incidence  
2 of parotid involvement is in the range of 10%-62% of cases, but  
3 they did not mention about a necessity of parotidectomy in early  
4 stages. Several surgeons performed a prophylactic superficial  
5 parotidectomy as a standard of care<sup>14)-16)</sup>, but others did not  
6 accept this because there seems to be no survival benefit of a  
7 prophylactic parotidectomy<sup>5), 17)</sup>. Hosokawa et al<sup>18)</sup> suggested that  
8 if the tumor invaded anterior-inferior wall of canal,  
9 parotidectomy was recommended.

10 In our series, no T1 and T2 diseases invaded parotid gland  
11 directly, and only one patient with T2 tumor had potential  
12 parotid gland lymph node metastasis at the time of initial  
13 diagnosis. Fortunately, the recurrence tumor was successfully  
14 salvaged by superficial parotidectomy without facial nerve  
15 paralysis. In the present study, the rates of potential parotid  
16 gland lymph node metastasis in T1 and T2 were 0% (0/14) and 5%  
17 (1/19) respectively. That is significantly lower than the  
18 previous reports. The possible explanation of this discrepancy  
19 is the accuracy of the preoperative assessment of extent of  
20 disease. As mentioned above, the extents of the diseases were  
21 precisely assessed by contrast and thin-sliced CT scan, MRI, and  
22 FDG-PET in our series. The patients in the previous reports may  
23 include underdiagnosed advanced diseases. Taken together,  
24 present results suggest that prophylactic superficial

1 parotidectomy is not mandatory in T1 disease and in T2 disease  
2 without tumor in anterior or inferior canal wall. However,  
3 precise preoperative assessment and careful follow-up are  
4 mandatory using diagnostic imaging including high-resolution CT  
5 scan, MRI and FDG-PET.

6 A necessity of prophylactic neck dissection in T1 and T2  
7 patients is also controversial. Gidley et al<sup>16)</sup> suggested  
8 selective neck dissection (level II-III) for T1 or T2 patients.  
9 Prasad et al<sup>13)</sup> proposed that they examined frozen section of  
10 level II lymph node, then dissected neck lymph node only when  
11 histology of frozen section showed positive metastatic cancer.  
12 However, in the present study, no neck LN metastasis was  
13 observed in any of the 37 patients not only at the time of  
14 initial diagnosis but also during the all the follow-up period.  
15 Thus, we believe that prophylactic neck dissection is not  
16 necessary for T1 and T2 patients<sup>19)</sup>, as long as precisely extent  
17 of tumor is assessed by imaging as mentioned above.

18 As for PORT, UK guidelines recommend post-operative (C)RT  
19 for most of T2-T4 with the exception of T1 and selected T2  
20 without particularly peri-neural infiltration and with clear  
21 margins. In accordance with UK guidelines, many authors  
22 recommended PORT in T2 patients<sup>2), 3) 16)</sup>, especially in case with  
23 close or positive surgical margins, peri-neural invasion, or  
24 vascular invasion. Oya et al<sup>20)</sup> reported meta-analysis of PORT

1 for early stage patients. Survival analysis of all patients  
2 showed no differences between the surgery-only and PORT groups.  
3 However, PORT exhibited a better prognosis than surgery alone in  
4 T1 patients. They indicated that PORT can be the standard  
5 therapy for T1 and T2 patients. In the present series, we  
6 recommended PORT only for the patients with positive surgical  
7 margins in T1 and T2. As a result, 4 patients had positive  
8 surgical margins and 3 of them underwent PORT and have been  
9 alive without recurrence during the observation period. In the  
10 present study, local recurrence occurred in only one patient  
11 treated by sleeve resection, who was successfully salvaged by  
12 LTBR. Indeed, complete resection without positive surgical  
13 margins is essential for the treatment of the patients with T1  
14 and T2. However, PORT should be considered for patients with  
15 positive surgical margins. In our case series, we have not  
16 recommended PORT to the patients with perineural invasion,  
17 vascular invasion, or bone invasion, but almost all patients  
18 with these elements have not had local recurrence except for  
19 only one patient who was salvaged by operation.

20 This study has some limitation due to the retrospective  
21 nature. Firstly, sample size is very small for a meaningful  
22 decision. However, the rarity of EAC cancer makes it difficult  
23 to perform well-designed analysis at a single institution. The  
24 retrospective chart review is an important method for gathering

1 clinical data on outcomes, aiding clinical decision-making.  
2 Secondly, selection criteria for parotidectomy is not completely  
3 constant case by case.

4

5 Conclusion

6 Complete resection without positive surgical margins is  
7 essential for the treatment of the patients with T1 and T2 ear  
8 cancers. Prophylactic superficial parotidectomy or neck  
9 dissection is not mandatory for T1 and T2 diseases, as long as  
10 precisely extent of disease is assessed preoperatively. PORT  
11 should be performed for the patients with positive surgical  
12 margins.
