#### \*Highlights (for review)

#### Highlights

- First quantitative study of fetomaternal transfer of CLO and its metabolites
- Highly accurate quantification using LC-MS/MS analysis
- Clear demonstration of the rapid passage of CLO through the placental barrier
- Metabolite-dependent differences observed in blood pharmacokinetics and residual levels

Neonicotinoids (NNs), a widely used class of systemic pesticides, are regarded as exhibiting selective toxicity in insects. However, NNs are suspected of exerting adverse effects on mammals as well, including humans. To date, only adult male animal models have been subjected to general toxicity studies of NNs: fetuses have vet to be considered in this context. Here, we focused on the NN clothianidin (CLO) for the first quantitative LC-MS/MS analysis of maternal-to-fetal transfer and residual property of once-daily (single or multiple days), orally administered CLO and its metabolites in mice. The results revealed the presence of CLO and its five metabolites at approximately the same respective blood levels in both dams and fetuses. In the dams, CLO showed a peak value 1 h after administration, after which levels rapidly decreased at 3 and 6 h. In the fetuses of each group, levels of CLO were almost the same as those observed in the corresponding dams. The present results clearly demonstrated rapid passage of CLO through the placental barrier. However, metabolite-dependent differences observed in blood pharmacokinetics and residual levels. This is the first quantitative demonstration of the presence of CLO and its metabolites in fetal mouse blood.

The systemic pesticides collectively referred to as "neonicotinoids" (NNs) are chemically similar to nicotine. While NNs have been thought to exhibit low toxicity in birds and mammals, they are known to exert agonistic effects on the nicotinic acetylcholine receptors (nAChRs) of insects, affecting their central nervous system and leading to eventual paralysis and death (Ihara et al., 2003; Tomizawa and Casida, 2005). These systemic pesticides are taken up by, and transported throughout, plants, thereby protecting them from harmful insects for extended durations. In birds and mammals, the NNs have been shown to cause less toxicity than organophosphate and carbamate insecticides (Tomizawa and Casida, 2005). Vertebrates and insects have differently composed receptor subunits and receptor structures, which accounts for the higher affinity of NNs for the nAChRs of insects than for their counterpart vertebrate receptors (Latli et al., 1999; Tomizawa and Casida, 2005). However, recent studies have reported reproductive toxicity in quails (Tokumoto et al., 2013; Hoshi et al., 2014) and adverse neurobehavioral effects in mice and rats (Hirano et al., 2015, 2018; Dhouib et al., 2017; Takada et al., 2018; Yoneda et al., 2018). In addition, it has been shown that exposure of perinatal mice to NNs causes abnormalities in germ cells (Yanai et al., 2017) and induction of anxiety-like behaviors (Tanaka, 2012; Sano et al., 2016) in their offspring. Such studies have suggested that NNs are almost certainly transferred from mother to fetus. Epidemiological investigations have also detected NNs in the urine of Japanese adults (Ueyama et al., 2015) as well as Japanese children (Ikenaka et al., 2019). It is therefore generally assumed that humans are indeed exposed to NNs on a daily basis. The residue standard of pesticides is set based on the acceptable daily intake (ADI) value calculated from the results of animal toxicity studies, in which almost exclusively adult individuals have been examined. Generally, fetuses are more sensitive to potentially toxic chemicals than are adults. Even if safe for adults, pesticides are not always equally safe for fetuses. At the very least, fetal safety studies require the collection of data regarding the extent to which pesticides are transferred from mother to fetus. Some chemicals have previously been reported in samples of umbilical cord blood (Todaka and Mori, 2002), thereby demonstrating fetal exposure. However, no quantitative or timedependent analyses of maternal-to-fetal transfer of NNs have been reported.

The potency and effectiveness of NNs are determined primarily by the structural features of the overall molecule (Tomizawa and Casida, 2005). The molecular structures change with metabolism, producing several different metabolites (Roberts and Hutson, 1999; Klein, 2001, 2003; Environmental Protection Agency, 2003). Due to such changes, certain metabolites exhibit reduced affinity for insect receptors and increased affinity for mammalian receptors (Casida, 2011). A desmethyl metabolite of the NN thiamethoxam causes single-cell necrosis and an increase in apoptosis in the mouse liver (Green *et al.*, 2005). Such findings demonstrate the importance of including consideration of metabolites in investigations of NN toxicity.

For this study, we selected clothianidin (CLO), one of the NNs reported to cause

neurobehavioral effects in mice (Hirano et al., 2015, 2018). We then performed a

quantitative analysis of maternal-to-fetal transfer of CLO and its metabolites in mice.

#### 2. Materials and methods

97 2.1. Experimental animals and procedure

Male and female ICR mice (8-12 weeks old) were purchased from Japan SLC (Hamamatsu, Shizuoka, Japan). All mice were maintained in individual ( $40.5 \times 20.5 \times 18.5$  cm) ventilated cages (Sealsafe Plus Mouse; Tecniplast, Buguggiate, Italy) under controlled temperature ( $23 \pm 2^{\circ}$ C) and humidity ( $50 \pm 10\%$ ) on a 14-h light/10-h dark cycle at the Kobe University Life-Science Laboratory with *ad libitum* access to a pellet diet (DC-8; Clea Japan, Tokyo, Japan) and water. Female mice in proestrus were mated 1:1 with males overnight, and females that had a vaginal plug at 12:00 noon the following day were designated as being at embryonic day (E) 0.5. We administered CLO (purity: 95%, extracted from Dantotsu® Sumitomo Chemical Co., Tokyo, Japan; Hirano *et al.*, 2015) or vehicle (0.5% carboxymethylcellulose, 10 mL/kg) to pregnant ICR mice by oral gavage, and the treatment group was divided into a single-dose administration group and a daily (4 or 9 days) single-dose administration group (Fig. 1). In all groups (n = 5-6 mice)

in each group), the administration concentration was set to 65 mg/kg/day with reference to the no-observed-adverse-effect level (NOAEL) of 65.1 mg/kg from a 78-wk dietary carcinogenicity study in female mice (Food and Agriculture Organization of the United Nations, 2016; Uneme *et al.*, 2006), and two to four fetuses were selected from each dam. The single-dose administration group was divided into 4 subgroups, and blood was collected from the dams (posterior vena cava) and the fetuses (heart) under anesthesia with isoflurane at 1, 3, and 6 h after CLO administration on E18.5, respectively, after which, the animals were euthanized (Fig. 1A). The daily single-dose administration groups received CLO once per day from E10.5 and E15.5 to E18.5, and blood was collected from the mice 6 h after the final administration of CLO by the method described above (Fig. 1B). The groups were designated by time of administration as CLO-1h, CLO-3h, CLO-6h, CLO4d-6h, CLO9d-6h. This study was approved by the Institutional Animal Care and Use Committee (Permission #26-05-07) and was carried out according to the Kobe University Animal Experimentation Regulations.

#### 2.2. Chemicals

- The CLO standard (purity: 99.9%) was purchased from Fluka (Buchs, Switzerland).
- 127 The CLO-d3 (purity: >97.0%) was purchased from Hayashi Junyaku (Osaka, Japan). The
- 128 1-methyl-3-nitroguanidine (MNG) (purity: >98.0%) was purchased from Tokyo
- 129 Chemical Industry (Tokyo, Japan). Desmethyl-CLO (dm-CLO), desmethyl-desnitro-
- 130 CLO (dm-dn-CLO), desnitro-CLO (dn-CLO) and CLO-urea were synthesized at Toho
- 131 University (Supplement data).

#### 133 2.3. Extraction of neonicotinoids from blood samples

Here, 100 µl of 100-ppb CLO-d3 were placed in a 10-ml glass test tube as an internal standard substance. After the addition of 10 µl of blood and mixing the sample well, 0.5 ml of 1% formic acid in acetonitrile was added for protein precipitation. The tube contents were then briefly vortex-mixed. Then, 0.5 ml of acetonitrile and 0.5 ml of methanol were added to the tube, and the contents were each briefly vortex-mixed. The contents were

139 then sonicated for 10 min. Samples of supernatant were separated and used for the next 140 extraction and purification step. Two types of solid-phase extraction cartridges, InertSep 141 Phospholipid Remover (PR) (GL Science, Tokyo, Japan) and InertSep PSA (PSA) (GL 142 Science), were connected in series (PR, top; PSA, bottom) and the samples were 143 conditioned by the addition of 3 ml of acetonitrile. The samples were passed through the 144 PR/PSA cartridges, and the eluents were collected in new test tubes (Fraction 1). After 145 0.5 ml of acetonitrile and 0.5 ml of methanol were sequentially passed through the 146 PR/PSA cartridges, the PR was removed. Fraction 2 was also collected in the same test 147 tube as that used for Fraction 1 (fraction 1+2). Furthermore, 3 ml of acetonitrile was 148 passed through the PSA cartridge to elute all neonicotinoids, and the eluents were 149 collected in the same test tube (Fraction 1+2+3). The collected eluents were evaporated 150 to dryness using a centrifugal concentrator (CVE-200D with UT-2000, Eyela, Tokyo, 151 Japan). The samples were then reconstituted with 200 µl of 20% methanol aqueous solution containing 100 ppb Cotinine-d3. Then they were transferred to a 1.5-ml tube and 152 153 centrifuged at 10,000 G for 10 min. The supernatant was transferred into an HPLC vial 154 for LC-MS/MS analysis. 155 An LC-ESI/MS/MS (Agilent 6495B, Agilent Co., CA, USA) system equipped with 156 Kinetex Biphenyl (2.1 mm ID × 100 mm, Ø 2.6 μm) (Phenomenex, Inc., CA, USA) was 157 used for the sample analysis. Solvents A and B used for the HPLC analysis were 0.1% 158 formic acid + 10 mM ammonium acetate water solution and 0.1% formic acid + 10 mM 159 ammonium acetate methanol solution, respectively. The gradient was programmed as 160 follows: t = 0 to 1 min: 5% B (isocratic), t = 6 min: 95% B (gradient), t = 6 to 8 min 161 (gradient): 95% B (isocratic). The column oven temperature and flow rate were 60°C centigrade and 0.5 ml/min, respectively. Detection of target compounds was performed 162 163 by multiple-reaction monitoring (MRM) in positive ionization mode as described in Table 164 1. The recovery rates of clothianidin and its metabolites were in the range of  $62.1 \pm 7.1\%$ (MNG) to  $92.3 \pm 8.5\%$  (dm-CLO). In addition, the reproducibility of the analysis system 165 166 was confirmed by single or multiple analysts, with a relative standard deviation (RSD) of 167 10% for all compounds.

169

#### 2.4. Data analysis

170 Statistical analyses were performed with Excel Statistics 2012 (Version 1.00, SSRI, 171 Tokyo, Japan). Levels of CLO and dm-CLO were analyzed by one-way ANOVA followed 172 by the Tukey-Kramer post hoc test. Levels of other chemicals were analyzed by Kruskal-173 Wallis test followed by Steel-Dwass test. The results were considered significant when 174 the p-value was less than 0.05. The correlation between dams and fetuses regarding the 175 blood levels of CLO and dm-CLO were assessed using Pearson's correlation coefficient 176 analysis, and those of dm-dn-CLO, dn-CLO, CLO-urea, and MNG were done using 177 Spearman's rank correlation coefficient analysis.

178

179

181

#### 3. Results

3.1. Blood pharmacokinetics of CLO and its metabolites in dams and fetuses

In the present study, CLO and its five metabolites were detected not only in dams but

182 also in the fetuses. There are several metabolic pathways for CLO. Here, we detected 183 desmethyl-CLO (dm-CLO), a major metabolite of CLO in mice that is generated by 184 demethylation of the methyl group of CLO. When dm-CLO is metabolized, the nitro 185 group is reduced to form desmethyl-desnitro-CLO (dm-dn-CLO). Thus, CLO forms not 186 only dm-CLO but also desnitro-CLO (dn-CLO) by reduction of the nitro group, and MNG 187 is formed from CLO by cleaving the thiazolyl chlorine substituent. Then, dn-CLO is 188 further metabolized to CLO-urea by cleavage of the imino group (Fig. 2). 189 Blood levels of CLO in both the dam and fetus groups were significantly higher in the 190 CLO-1h group (dams  $23.69 \pm 2.10$  ppm, fetuses  $20.46 \pm 1.10$  ppm) than in the CLO-3h 191 group (dams  $16.19 \pm 2.58$  ppm, fetuses  $14.48 \pm 0.84$  ppm), and blood levels in the CLO-192 3h group were significantly higher than in the CLO-6h group (dams  $7.29 \pm 0.99$  ppm, 193 fetuses  $5.91 \pm 0.43$  ppm) (Fig. 3A). On the other hand, the blood levels of dm-CLO in the 194 CLO-3h group (dams  $10.97 \pm 1.01$  ppm, fetuses  $7.28 \pm 0.32$  ppm) and the CLO-6h group 195 (dams  $10.27 \pm 1.05$  ppm, fetuses  $6.50 \pm 0.39$  ppm) were significantly higher than in the 196 CLO-1h group (dams  $5.53 \pm 0.34$  ppm, fetuses  $2.90 \pm 0.17$  ppm) (Fig. 3B). The blood levels of dm-dn-CLO in the CLO-6h group of dams (0.036 ± 0.002 ppm) were significantly higher than those in the CLO-1h group of dams  $(0.022 \pm 0.004 \text{ ppm})$ ; however, in the fetuses there was no corresponding significant difference, although a tendency was observed by which dm-dn-CLO levels increased with time (Fig. 3C). The blood levels of fetal dn-CLO in the CLO-6h group  $(0.049 \pm 0.004 \text{ ppm})$  were significantly lower than those in the CLO-3h group  $(0.068 \pm 0.005 \text{ ppm})$ . Although the difference was not statistically significant, dams in the CLO-6h group (0.050  $\pm$  0.006 ppm) had lower blood levels of dn-CLO than those in the CLO-3h group  $(0.061 \pm 0.013 \text{ ppm})$  (Fig. 3D). The blood levels of CLO-urea in both dams and fetuses gradually decreased over time. In the dams, the blood levels of CLO-urea in the CLO-6h group (0.039  $\pm$  0.004 ppm) were significantly lower than those in the CLO-1h group (0.084  $\pm$  0.009 ppm), and in the fetuses, blood levels of CLO-urea in the CLO-6h group (0.039  $\pm$  0.003 ppm) were significantly lower than those in both the CLO-1h group (0.071  $\pm$  0.005 ppm) and the CLO-3h group  $(0.055 \pm 0.003 \text{ ppm})$  (Fig. 3E). The blood levels of MNG were highest in the CLO-3h group in both dams (0.307  $\pm$  0.051 ppm) and fetuses (0.167  $\pm$  0.010 ppm) (Fig. 3F).

#### 3.2. Maternal-fetal ratio of levels of CLO and its metabolites in the blood

There was a positive correlation between the blood levels of maternal CLO and its metabolites and those of the offspring. The ratio of blood levels of each substance in the fetus to those in the dam were 85.0% for CLO (Fig. 4A), 63.0% for dm-CLO (Fig. 4B), 84.5% for dm-dn-CLO (Fig. 4C), 96.7% for dn-CLO (Fig. 4D), 84.0% for CLO-urea (Fig. 4E), and 47.2% for MNG (Fig. 4F). For all compounds, blood levels in the fetus were lower than those in the dams.

221

223

224

225

#### 3.3. Residual levels of CLO and its metabolites in the blood

Since the transfer of CLO to the fetus was confirmed as described above, it was administered daily for the purpose of confirming its residual property in both the dams and fetuses. However, as regards maternal blood CLO levels, there was no significant

226	difference between the CLO-6h group (7.28 $\pm$ 0.99 ppm), the CLO4d-6h group (7.84 $\pm$
227	0.74 ppm), and the CLO9d-6h group (6.67 $\pm$ 0.90 ppm). On the other hand, the blood
228	CLO level in the fetus was significantly higher in the CLO4d-6h group ( $6.57\pm035$ ppm)
229	than in the CLO9d-6h group (5.00 $\pm$ 0.31 ppm) (Fig. 5A). As regards dm-CLO, no
230	significant differences were observed between groups of dams, nor between groups of
231	fetuses (Fig. 5B). In the case of dm-dn-CLO, the blood level of dams was significantly
232	higher in the CLO9d-6h group (0.048 $\pm$ 0.004 ppm) than in the CLO4d-6h group (0.029
233	$\pm$ 0.004 ppm). As regards the corresponding fetal blood levels, those in the CLO9d-4h
234	group (0.033 $\pm$ 0.001 ppm) were significantly higher than those in both the CLO4d-6h
235	group (0.022 $\pm$ 0.001 ppm) and the CLO-6h group (0.029 $\pm$ 0.003 ppm), and those in the
236	CLO-6h group were significantly higher than in the CLO4d-6h group (Fig. 5C). In the
237	case of dn-CLO, maternal blood levels were significantly higher in both the CLO-6h
238	group (0.050 $\pm$ 0.006 ppm) and the CLO9d-6h group (0.053 $\pm$ 0.003 ppm) than in the
239	CLO4d-6h group (0.034 $\pm$ 0.002 ppm). Likewise, in the fetus, the CLO9d-6h group (0.046
240	$\pm~0.003$ ppm) had significantly higher levels of dn-CLO than those in the CLO4d-6h
241	group (0.038 $\pm$ 0.003 ppm) (Fig. 5D). As regards CLO-urea, no statistically significant
242	differences were seen in maternal blood levels between groups, although the levels in the
243	CLO9d-6h group (0.030 $\pm$ 0.003 ppm) were lower than those in the CLO4d-6h group
244	$(0.046 \pm 0.009 \text{ ppm})$ . As for CLO-urea in the fetal blood, the level in the CLO9d-6h group
245	(0.029 $\pm$ 0.002 ppm) was significantly lower than that of the CLO4d-6h group (0.036 $\pm$
246	0.003 ppm) (Fig. 5E). Regarding MNG, the blood levels of the dams were not
247	significantly different between groups, but the CLO4d-6h group (0.144 $\pm$ 0.020 ppm) had
248	a higher level of MNG than that in the CLO9d-6h group (0.111 $\pm$ 0.012 ppm). On the
249	other hand, fetal blood levels of MNG were significantly higher in the CLO4d-6h group
250	$(0.109 \pm 0.006 \text{ ppm})$ than in the CLO9d-6h group $(0.083 \pm 0.005 \text{ ppm})$ (Fig. 5F).

251

252

#### 4. Discussion

253 This study was the first to quantitatively confirm the transfer of CLO and its metabolites 254 from dam to fetus in a mouse model. A time-dependent decrease in blood levels of CLO 255 was observed in dams and fetuses in the single-dose administration group. 256 On the other hand, dm-CLO increased from 1 to 3 h after administration. Although the 257 blood levels of dm-dn-CLO increased from 1 to 6 h, the levels of CLO-urea decreased 258 with time. In the case of MNG, a peak was observed 3 h after the administration of CLO. 259 From these findings, it was determined that the behavior of metabolites varies. This 260 differential finding regarding the blood pharmacokinetics of CLO metabolites is thought 261 to be due to differences between rapidly metabolized substances and those that are slower 262 to metabolize. When the blood concentrations of maternal and fetal substances were 263 compared, no substance-dependent differences were found to be associated with placental 264 barrier permeability. 265 It is thought that variants of Cytochrome P450 (CYPs) are related to the metabolism of 266 neonicotinoids (Shi et al., 2009). Since most CYPs are negligibly expressed in fetal mice, 267 it is expected that fetuses would not possess any capacity for CLO metabolism (Kitaoka 268 et al., 2018). In fact, it is highly unlikely that a fetus could metabolize CLO transferred 269 from the dam because the blood levels of CLO metabolites in the fetus were not higher 270 than those of the dam. In addition, it was found that CLO crossed the placental barrier 271 very quickly because it was transferred to the fetus at a high rate of 86% [CLO-1h group 272 (fetus / maternal:  $20.46 / 23.69 \times 100$ )] of the maternal blood level 1 h after CLO 273 administration. Furthermore, it was not only CLO that crossed the placental barrier 274 quickly, but also dm-CLO at a rate of 63.0%, dm-dn-CLO at 84.5%, CLO-urea at 84.0%, 275 and dn-CLO at 96.7%. These findings reveal that CLO and its metabolites were hardly 276 inhibited by the placental barrier. 277 There were no significant differences observed in the blood CLO levels of the dams 278 between the multiple days-of-exposure groups. In fetuses, the 4-day group showed 279 significantly higher values than those of the 9-day group. From these findings, it can be 280 concluded that the metabolism of the parent compound (CLO) is very fast and there is 281 almost no residual property of CLO in the blood. On the other hand, dm-dn-CLO and dnCLO levels were lower in the 4-day administration group than in the 1-day administration group, and higher in the 9-day administration group than in the 4-day administration group, respectively. While it is thought that CLO exhibits little residual property, the same cannot be concluded about its metabolites. Of the five metabolites detected in this study, three substances (i.e., not dm-dn-CLO or dn-CLO) were found at lower levels or almost the same level in the 9-day group compared to the 4-day group. Thus, it will still be necessary to conduct experiments that include longer-term exposures.

Here, dn-CLO was detected in both dams and fetuses. Imidacloprid, a neonicotinoid, is metabolized to a desnitro form, thereby increasing affinity for mammalian target receptors (Casida, 2011). Similarly, dn-CLO has a higher affinity for mammalian target receptors than insects' ones (Casida, 2011). Taken together, these structural and metabolic findings contribute to the elucidation of the effects of CLO on mammals. However, it has been confirmed that the desnitro metabolic reaction is not active specifically in mice, since levels were several hundredths of those of dm-CLO.

Neurobehavioral effects and germ cell abnormalities in adult mice have been reported as effects of exposure to CLO (Hirano *et al.*, 2015, 2018; Yanai *et al.*, 2017). Likewise, mild focal necrosis with swollen cellular nuclei, hypertrophied blood vessels and cytoplasmic lesions in the mouse liver, and degeneration of the tubules and glomeruli in the kidney have been reported to be induced by imidacloprid (Arfat *et al.*, 2014), as has suppression of humoral and cellular immune responses by thiamethoxam (Salema *et al.*, 2016). The results of this study revealed that fetuses are also exposed to CLO at the same level as that in adults. Given that fetuses are thought to be more sensitive to chemicals than adults (Needham and Sexton, 2000; Charnley and Putzrath, 2001; Mori, 2004), the present findings raise concern about the potential for more serious adverse effects of CLO on fetuses. Neurobehavioral effects have been confirmed in male mice after the administration of CLO, even with the administration of one-tenth of the NOAEL dose (Hirano *et al.*, 2018), which is close to the assumed acceptable daily intake (ADI); therefore, it is reasonable to extrapolate that CLO would also affect fetuses. The current NOAEL setting takes into account intake by adults only. Thus, the NOAEL values should

311 be recalculated to include non-adults, considering that fetuses would be exposed to toxins 312 at the same levels as the dam. The ADI is calculated based on the NOAEL settings, and 313 the residual standard value for food pesticide residues are set with reference to the ADI. 314 Because there are NOAEL- and ADI-related concerns about effects on fetuses, it will be 315 necessary to review the pesticide residual standard value of CLO. 316 In conclusion, the placental transfer of CLO was confirmed quantitatively for the first 317 time in the present study. Specifically, this is the first report to quantitatively detect an 318 NN, as well as its metabolites, in fetal blood. The fetuses are also potentially threatened 319 by some metabolites which might have higher affinity for mammalian nAChRs than the 320 parent compound (CLO). The present results thus provide important data for future

322

#### FIGURE LEGENDS

#### Fig. 1. Outline of the experiments

- 438 (A) Scheme showing the overall experimental design of a single-dose administration of
- 439 CLO. CLO was orally administered to pregnant ICR mice at embryonic day 18.5 (E18.5).
- The single oral administration group was divided into three subgroups each of dams and
- fetuses (total=six groups), from which blood samples were obtained at 1, 3, and 6 h after
- 442 CLO administration. The vehicle group was treated with 0.5% carboxymethyl-cellulose,
- and blood samples were collected 1 h after the administration of vehicle, as in the CLO-
- administration groups.
- (B) Scheme showing the overall experimental design of a daily single-dose administration
- of CLO. To examine CLO residual property, the CLO-6h group received a single dose at
- E18.5, the CLO4d-6h group received four doses at E15.5-18.5, and the CLO9d-6h group
- received nine doses at E10.5-18.5. Blood was collected in the same manner as described
- in Fig. 1A after 6 h of the last CLO administration.

450

436

437

- 451 **Fig. 2.** Partial metabolic pathway of CLO in mice
- Demethylation of the CLO methyl group forms dm-CLO, and dm-dn-CLO is produced
- by further reduction of the dm-CLO nitro group. Reduction of the nitro group of CLO
- 454 produces dn-CLO, which in turn cleaves the imino group of dn-CLO to produce CLO-
- 455 urea. Metabolic cleavage of the thiazolyl choline group of CLO produces the substance
- 456 1-methyl-3-nitroguanidine (MNG).

457

- 458 Fig. 3. Blood pharmacokinetics of CLO and its metabolites in dams and fetuses
- The parent compound (CLO) and its metabolites detected in maternal and fetal blood
- 460 after a single CLO administration are shown. The blood pharmacokinetics showed
- various behaviors for each substance, but the dynamics were similar between the dams
- and fetuses. Values are mean  $\pm$  SE. \*P<0.05. The number of samples: CLO-1h (dam = 6,
- 463 fetus = 24), CLO-3h (dam = 6, fetus = 22), CLO-6h (dam = 6, fetus = 23)

464

465 Fig. 4. Maternal-fetal ratio of blood levels of CLO and its metabolites 466 The fetus-to-mother ratio of blood levels of CLO and its metabolites in the single-dose 467 group. The horizontal axis (coordinates) shows the blood concentrations of the mothers 468 and the vertical axis (coordinates) shows the blood concentrations of the offspring. The 469 number of samples: CLO-1h (dam = 6, fetus = 24), CLO-3h (dam = 6, fetus = 22), CLO-470 6h (dam = 6, fetus = 23)471 472 Fig. 5. Residual levels of CLO and its metabolites in the blood of dams and fetuses 473 Residual levels of the parent compound (CLO) and its metabolites detected in maternal 474 and fetal blood after a daily single-dose CLO administration are shown. The blood 475 pharmacokinetics showed various behaviors for each substance (A-F), but the general 476 dynamics were similar between the dams and fetuses. Values are mean  $\pm$  SE. \*P<0.05. The number of samples: CLO-6h (dam = 6, fetus = 23), CLO4d-6h (dam = 5, fetus = 20), 477 478 CLO9d-6h (dam = 7, fetus = 28)479 480 481 482

Table 1: Multiple-reaction monitoring (MRM), retention times (RT), recovery rate, and limit of quantification (LOQ) of target chemicals

Chemicals	MRM	Qualifier ion	RT	Recovery rate (%±SD)	LOQ (ng/ml)
Clothianidin	250.02>132.00	169.1	3.9	86.3 ±6.4	0.5
Clothianidin-d3	253.04>132.10	171.9	3.9	86.8 ±7.2	_
dm-Clothianidin	236.00>132.00	113.1	2.9	$92.3 \pm 8.5$	1.0
dm-Clothianidin-urea	192.00>132.10	86.1	1.8	77.1 ± 7.6	5.0
Clothianidin-urea	206.02>86.2	175.0	2.6	82.5 ±11.0	0.5
dn-Clothianidin	205.03>132.1	45.1	1.3	$72.2 \pm 6.3$	0.5
dm-dn-Clothianidin	191.02>132.1	45.2	1.2	74.4 ±7.2	1.0
MNG	119.10>73.02	57.2	1.0	62.1 ±7.1	0.5
